Resource sustainability: a Lithium's tale

Francesco Di Benedetto

University of Ferrara

The global societal metabolism, nowadays mostly supplied by energy chemically stored in the fossil fuels, is facing a transition towards renewables. What industrial/economical choices are really viable in this time? There are constraints from the resource availability and management? The short course aims at thinking to these questions, using the Lithium case study as exemplar paradigm. Considerations on the present and future resource availability and on the best way to model it will be provided.
